Area of focus: Logo/Website Layout

Application Name

GitGoodBooks

Application description

Book tracking and suggestion platform where users can enter books they've previously read and want to read. The application can suggest books a user may like based on previously read genres and ratings using Google Books API.

Standardebooks.org is a platform to find ePUB's in the public domain (for use with e-readers/other digital methods of reading. Their API can be used to show if an ePUB is available for a given book listing. (https://standardebooks.org/feeds)

Additional features to consider adding: user interactions, leaving book reviews, friending other users, book club meetings, etc.

Audience

Anyone trying to find new books for their book clubs. Largely 20-40 year old people, but everyone is welcome.

Vision statement

For readers, who have grown tired of Goodreads and their commercialized use on Amazon. The GitGoodBooks is a book review website that recommends books based on previous reads and provides resources for free access to books. Unlike Goodreads, our product is not affiliated with Amazon (evil), and is not used to advertise or sell books.

Version control

Repository link: https://github.com/Epion42/gitgoodbooks

Development methodology

We will be using an agile methodology to implement all the features. We will take advantage of Kanban-like visual boards to track progress as well as weekly scrum check-ins.

Communication plan

We will be communicating via Discord for the majority of the project. We will be using it for meetings as well as general discussion and idea sharing.

Meeting plan

Team meetings are done remote via Discord, utilizing voice chatting and screensharing
Weekly TA meetings will be done from 4:35 - 4:50PM each Monday at ***[room pending]***

Use case diagram

See UseCaseDiagram.pdf

Extra credit

(five risks)

- Users injecting their own html into text input boxes, that we want to allow users to save their comments and such with html formatting. The mitigation to this is to use the npm

package sanitize-html where we can configure what tags and other things are allowed. More specifically, this is to prevent XSS.

- SQL injections by parsing SQL into HTTP queries and parameters. The mitigation to this is to use $ parameters with [...].
- Users spamming bad words, such as the n-word in reviews or book forums. This could be mitigated by simply adding a filter that blocks certain words from being submitted.
- Users spamming words in general, or spamming capitals. This could be mitigated by certain checks to see if X amount of words appear in a row, or if 20 characters appear capitalized in a row etc.
- Password vulnerabilities that could be accessed by bad actors. We will implement a hashing system using bcrypt with salts and store only hashes in the db.
